## **Ecuador**

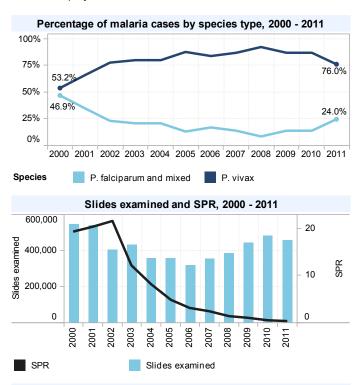

Ecuador has shown a dramatic decrease in malaria incidence achieving 99% reduction compared to the year 2000, surpassing its Millennium Development Goal (MDG). The country is presently in pre-elimination phase. Proportion of cases due to Plasmodium falciparum and mixed infections has followed a similar trend from almost 47% of all cases to 14% in 2011. One death due to malaria was reported in 2011.

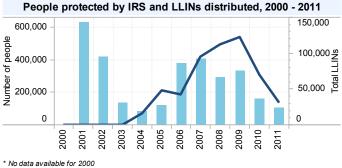

Guayas, Esmeraldas and Canar, all on the western side of the country, reported 90% of all cases due to P. falciparum and mixed infections in the country in 2011. Anopheles albimanus is the principal vectoralong the pacific coast while A. darlingi abounds in the Amazon re-

Artemether and Lumefantrine is used for treatment of *P. falciparum*, and chloroquine and primaquine for P. vivax, a 14 day treatment regimen being followed for the former. Almost 68% of all cases were diagnosed and treated within the first 72 hours of appearance of symptoms, still short from the 80% considered to be ideal.

Coverage by indoor residual spraying (IRS) and insecticide treated bednets (ITNs) has been decreasing in recent years on account of decreasing malaria incidence, after having reached a peak in 2009. The proportion of cases in children less than 15 years has increased steadily from 23% in 2002 to 39% in 2011.

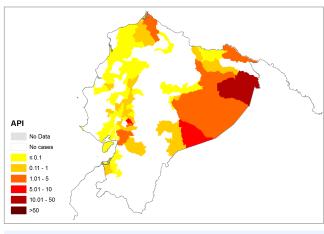

Funding by the government increased steadily till 2007 after which a steep fall was seen. A Global Fund project and funding from AMI-RAVREDA project aid malaria control.
